Unconscious Bias in Faculty and Leadership Recruitment: A Literature Review

Although women and minorities have made significant strides in achieving equality in the workplace, they are still underrepresented in the upper strata of organizations, including senior faculty and leadership positions at medical schools and teaching hospitals.\(^2\)

Within the last decade, social science researchers have pursued the theory of “unconscious bias” as one barrier to workplace equality that may persist despite a general commitment to increase diversity across the academic medicine workforce and other organizations. This Analysis in Brief reviews the scientific literature on the theory of unconscious bias, explores the role of unconscious bias in job recruitment and evaluations, and offers suggestions for search committees and others involved in hiring decisions at medical schools and teaching hospitals.

Background and Method

Unconscious bias refers to social stereotypes about certain demographics or groups of people that individuals form outside of their own conscious awareness. Social scientists argue that most people have some degree of unconscious bias because it stems from our natural tendency to make associations to help us organize our social worlds.\(^3\)

To analyze and present the most relevant studies on unconscious bias, I performed an extensive literature search and sorted articles by their research methodologies and focus.\(^b\)

The eight articles selected for this Analysis in Brief were specifically about career-related unconscious bias, except for those on the Implicit Association Test (IAT), which were included as background material because of their prevalence in the literature and their direct illustration of unconscious bias. Articles on career-related unconscious bias included methodologies of two types: experimental studies involving artificial workplace situations and examinations of unconscious bias in actual hiring and review practices. The implications about recruitment practices in academic medicine drawn from this literature review are generalized from the findings of unconscious bias in many fields.

### Results and Discussion

**Implicit Association Test**

Though not directly connected to career-related unconscious bias, studies involving the IAT receive the most support for the theory of unconscious bias in general. The IAT has consistently demonstrated that people unconsciously prefer white over black, young over old, and thin over fat, and that people have stereotypic associations

However, the literature suggests that those involved in hiring processes can take steps to mitigate some of the effects of unconscious bias in evaluating job candidates. These steps may include:

- Ask individuals involved in hiring processes to reflect on unconscious biases by taking the online version of the IAT (https://implicit.harvard.edu/).
- Create a more objective, structured interview process by (a) setting criteria or using objective measures to assess the skills needed for effective job performance; (b) administering training to all involved in the search and interview process on how to conduct structured interviews; and (c) using performance, satisfaction, and turnover rates of new hires to measure the effectiveness of the interview process.
- Be aware that recommenders of applicants may hold unconscious biases, and therefore may present skewed representations of applicants in their letters of recommendation.
- Consider that cultural differences can affect first impressions of candidates. For instance, the standard interview in the United States uses the criteria of self-confidence, goal orientation, enthusiasm, and leadership, even though these qualities may not be apparent in people of more reserved cultures.
- Reserve ample time for the interviews and evaluations of candidates, as sex bias emerges more when evaluators are under time pressure.

linking males with science and careers and females with liberal arts and family.4,5 Typically, the IAT requires test-takers to rapidly match individuals of different demographics to words and pictures of varying pleasantness. The quick associations that the test-takers must make reveal their unconscious biases. Additionally, the test-takers often complete a measure of conscious bias. Correlations between scores on the pairing task and the conscious bias scale are generally weak, suggesting that participants have unconscious biases.6

Career-related Unconscious Bias
Experimental studies of career-related unconscious bias generally involve participants’ rating the skills of equally experienced, fictitious job applicants who vary only by gender or race. As evidenced by the articles described in Table 1, studies of this type support the notion that, given equal weighting on all other variables, people prefer males over females, and white and Asian-American individuals over African-American and Mexican-American individuals in job positions. In contrast to these experimental studies, research in real-life settings highlights the practical ramifications of career-related unconscious bias. Real-life examinations provide evidence that unconscious bias affects decisions in actual hiring and evaluation processes. The articles displayed in Table 2 suggest that unconscious bias negatively affects female and black individuals in search and selection processes. Therefore, employers may be more likely to hire white males over individuals of other demographics for job openings. In contrast to studies involving the IAT, the studies in Tables 1 and 2, which do not address the level of consciousness of the participants’ biases, provide only indirect evidence of unconscious bias. However, most individuals believe that they hold fewer biases than the average person,7 so the findings of bias in these studies very likely demonstrate unconscious bias.

Implications for Faculty Recruitment Processes in Academic Medicine
As evidenced by the preceding examples, unconscious biases may affect evaluations and decisions made in recruitment processes in academic medicine.
